54 **Thermoplastic polyurethanes.**

57 The present invention concerns a thermoplastic polyurethane material which is the reaction product of (1) a mixture of (a) 0.86 to 0.98 mole equivalent of a polyester diol having the molecular weight of from 650 to 5,000 and (b) 0.02 to 0.14 mole equivalent of a polyether diol having the molecular weight of from 2,000 to 5,000, and (2) a difunctional chain extender with (3) an organic diisocyanate. These polyurethane materials exhibit high resistance to severe abrasion forces while retaining desirable mechanical properties and are useful for the manufacture of shoe soles, ski boots, ski bindings, conveyor belts and screens used by mining industry and the like.

**EP 0 379 149 A2**

## THERMOPLASTIC POLYURETHANES

The present invention relates to thermoplastic polyurethanes which have significantly improved abrasion resistance while retaining other desirable mechanical properties.

Preparation of thermoplastic polyurethane materials is well known in the art. Such materials can be extruded, injection molded and fabricated in other known manners to form many different shapes and configurations which find utility in a large number of application.

Thermoplastic polyurethane materials can be prepared by reacting polymeric polyols, diisocyanate compounds and polyfunctional chain extender compounds having active-hydrogen groups such as hydroxyl, primary amino, secondary amino, and mixtures thereof. Various combinations of polyester polyols and polyether polyols have been employed in the preparation of polyurethane materials having a diversity of properties.

U.S. Patent No. 3,493,634 discloses thermoplastic polyurethane elastomers prepared from a mixture of a polyester diol, polyoxyalkylene glycol and glycol extender.

U.S. Patent No. 3,798,200 and 3,963,681 disclose polyether mixtures in the preparation of soft crosslinked polyurethanes.

U.S. Patent No. 4,124,572 discloses blends of polyester polyols with particular polyoxypropylene-polyoxyethylene glycols which are said to have higher tensile strengths than prior art polyether and polyester based polyurethanes.

U.S. Patent No. 4,182,898 discloses the use of isocyanate terminated prepolymers prepared from a blend of polyester polyol and polyether polyol in the preparation of cast polyurethane elastomers.

U.S. Patent No. 4,379,904 discloses a thermoplastic polyurethane elastomer having improved impact properties prepared from 4,4-methylenebis(phenyl isocyanate), difunctional extender and particular polyoxypropylene polyoxyethylene copolymers and/or polyester diols.

British Patent No. 1,233,614 discloses polyurethanes having improved stiffness-temperature properties prepared by reacting an organic polyisocyanate with a mixture containing particular incompatible low and high molecular weight polyols.

British Patent No. 1,410,809 and its equivalent German Offenlegungsschrift 2,261,482 disclose a polyurethane elastomer prepared from a polyfunctional isocyanate, a curing agent and a mixture of polyethers having active-hydrogen terminal groups, wherein the weight average molecular weight of the polyether mixture is between 4,500 to 20,000 and the molecular weight distribution curve of the polyether mixture has at least two peaks. These polyurethane elastomer are alleged to have good cut growth and flex crack resistance properties.

British Patent Nos. 1,388,718 and 1,389,039 disclose a polyester-polyurethane product prepared by reacting a polymeric diol mixture comprising (a) 3-30 percent by weight of a high molecular weight poly-(alkylene alkanedioate) glycol or poly(oxycaproyl) diol and (b) 97-70 percent by weight of a low molecular weight (alkylene alkanedioate) glycol or poly(oxycaproyl) diol and which polymeric diols differ in the molecular weight by at least 1,000 with an organic diisocyanate and a difunctional chain extender. These materials are said to be better adapted for end uses such as in shoe soles and solid truck tires due to their improved split tear strength and elongation properties.

British Patent No. 1,155,548 discloses polyurethane materials particularly adapted to injection molding and having a good balance of physical properties. These polyurethanes are particularly designed to overcome the problems encountered by prior art materials in injections molding such as difficulty in filling mold cavities, sticking in the mold, shrinkage and long cycle times. These polyurethanes are prepared by reacting a mixture of 60-85 parts of a hydroxyl terminated existentially linear polyether having a molecular weight between 900 and 3,000, 15-40 parts of an essentially linear hydroxyl poly(alkylene oxide) having a molecular weight between 800 and 2,000 and 1.25-12.8 mols of an aliphatic glycol per mol of total hydroxyl polyester and hydroxyl poly(alkylene oxide) with an aryl isocyanate in a molar amount equal to the total mols of hydroxyl polyester, hydroxyl poly(alkylene oxide) and aliphatic glycol.

Thermoplastic polyurethane materials have become of increasing importance for use in manufacturing shoe soles, sport shoe soles and particularly ski boots. As demand has risen for such materials so have the physical property requirements increased, particularly requirements for resistance to high abrasive and destructive forces to which ski boots and sport shoe soles are constantly subjected to. Although the prior art is capable of producing polyurethane materials which can be used in these applications, there is still great need and demand for materials which will have considerably improved resistance to abrasion forces than the prior art material.

It has now been discovered that a thermoplastic polyurethane can be prepared which exhibits

surprisingly high resistance to abrasion forces while retaining a spectrum of other desirable chemical properties including high impact resistance and creep behaviour. This high resistance to abrasion forces is quite unexpected in view of the performance characteristics of similar prior art materials. The new thermoplastic polyurethanes are particularly useful in the manufacture of shoe soles, sport shoe soles, ski boots and bindings, various automotive uses such as car bumpers and side guards, conveyor belts and screens for use by mining industry, oil seals and the like.

The present invention concerns a thermoplastic polyurethane comprising the reaction product of (1) a mixture of (a) 0.86 to 0.98, preferably 0.88 to 0.95, most preferably 0.88 to 0.93, mole equivalent of a polyester diol having the molecular weight of from 650 to 5,000, preferably from 1,000 to 3,000, most preferably from 1,000 to 2,000 and (b) 0.02 to 0.14, preferably 0.05 to 0.12, most preferably 0.07 to 0.12, mole equivalent of a polyether diol having the molecular weight of from 2,000 to 5,000, preferably from 2,000 to 3,000 most preferably from 2,200 to 2,900 and (2) a difunctional chain extender with (3) an organic diisocyanate.

In another embodiment the present invention concerns a process for the preparation of a thermoplastic polyurethane which process is characterized by reacting (1) a mixture of (a) 0.86 to 0.98, preferably 0.88 to 0.95, most preferably 0.88 to 0.93, mole equivalent of a polyester diol having the molecular weight of from 650 to 5,000, preferably from 1,000 to 3,000, most preferably from 1,000 to 2,000 and (b) 0.02 to 0.14, preferably 0.05 to 0.12, most preferably 0.07 to 0.12, mole equivalent of a polyether diol having the molecular weight of from 2,000 to 5,000, preferably from 2,000 to 3,000 most preferably from 2,200 to 2,900 and (2) a difunctional chain extender with (3) and organic diisocyanate at an elevated temperature.

Still in another embodiment the present invention concerns the use of the thermoplastic polyurethane prepared by the above described process in the manufacture of shoe soles, ski boots and ski bindings.

The term "thermoplastic" is used in the generally accepted sense to those skilled in the art to mean, inter alia, the ability to be injection molded.

The thermoplastic polyurethanes of the present invention exhibit surprisingly considerably higher resistance to severe abrasion than the prior art materials while retaining a wide spectrum of other desirable mechanical properties such as high impact resistance and creep behaviour.

The polyester diols employed in the present invention are any of the conventional type polyester diols known to those skilled in the art. The polyester diols include both poly(alkylene alkanedioate) diols and poly(oxypropyl) diols.

The poly(alkylene alkanedioate) diols can suitably be prepared via well-known esterification techniques using a predetermined molar excess of an aliphatic glycol with relation to a dicarboxylic acid, e.g., see U.S. Patent No. 2,423,823. In general, poly(alkylene alkanedioate) diols are suitably prepared under reaction conditions of the order of 250° C. and higher, using low pressures, e.g., less than 1 mm Hg. Water of condensation is carefully removed from the reaction by conventional equipment suitable for such purposes. Desirably, dicarboxylic acids can be unsubstituted or substituted dicarboxylic acids which contain from 4 to 12 carbon atoms and include adipic acid, succinic acid, pimelic acid, suberic acid, azelaic acid, sebacic acid and the like. Adipic acid is the most preferred dicarboxylic acid. Illustrative of the aliphatic glycols which can be employed for the preparation of poly(alkylene alkanedioate) diols are ethylene glycol, 1,3-propylene glycol, 1,4-butanediol, 1,3-butylene glycol, 1,6-hexanediol and 1,12-dodecanediol. The aliphatic glycols preferably contain from 2 to 12 carbon atoms. Mixtures of the above aliphatic glycols and/or dicarboxylic acids can also be employed.

The poly(oxypropyl) diols contemplated by the present invention are well known in the art, e.g., see U.S. Patent No. 3,169,945, U.S. Patent No. 3,248,417 and U.S. Patent Nos. 3,021,309 to 3,021,317. A general procedure involves reacting a molar excess of epsilon-caprolactone with an initiator which contains two active hydrogen-containing groups, e.g., hydroxyl, primary amino, secondary amino and mixtures thereof, such groups being capable of opening the lactone ring whereby it adds as an open chain to the site of the active hydrogen-containing group. The reaction is conducted at an elevated temperature, preferably in the presence of a catalyst such as tetrabutyl titanate and stannous octoate for a period of time sufficient to produce the poly(oxypropyl) diols. By carefully controlling the purity and molar ratio of the reactants there are produced poly(oxypropyl) diols of the desired molecular weight.

Preferred species of the polyester diols contemplated by the present invention include poly(ethylene adipate) diols, poly(propylene adipate) diols, poly(butylene adipate) diols, poly(ethylene/butylene adipate) diols and poly(oxypropyl) diols. The most preferred polyester diol is poly(butylene adipate) diol.

Polyether diols contemplated for use in the present invention are well known, essentially linear, hydroxyl terminated materials having ether linkages as the major linkage joining carbon atoms. Illustrative polyether diols include poly(alkylene oxide)glycols such as poly(ethylene oxide) diol, poly(propylene oxide) diol, poly-(tetramethylene oxide) diol, block or random polyoxypropylene-polyoxyethylene copolymeric glycol or

polyoxytetramethylene-polyoxyethylene copolymeric glycol having an ethylene oxide content of from 5 to 40 and the like. The polyether diols can be capped with ethylene oxide. Illustrative capped polyether diols include ethylene oxide capped poly(propylene oxide) diol, ethylene oxide capped polyoxypropylene-polyoxyethylene glycols and the like. Poly(tetramethylene oxide) diol is the most preferred polyether diol.

Poly(alkylene oxide) glycols are produced in accordance with procedures well-known in the art; see for example, *Kunststoff Handbuch*, Band 7, Polyurethane, R. Vieweg, Carl Hansen Verlag, München 1966; and U.S. Patent No. 4,294,934. Suitably, poly(alkylene oxide) glycols are prepared by polymerizing epoxides such as ethylene oxide, propylene oxide, butylene oxide or tetrahydrofuran on their own, for example in the presence of Lewis catalysts such as boron trifluoride, or by addition of these epoxides preferably ethylene oxide and propylene oxide either in admixture or successively with starter components containing reactive hydrogen atoms such as water, alcohols, ammonia or amines.

Polyoxypropylene-polyoxyethylene copolymeric glycols contemplated for use in the present invention are well known in the art and typical embodiments are described in U.S. Patent No. 4,202,957. The polyoxypropylene-polyoxyethylene copolymeric glycols can be prepared by first polymerizing propylene oxide and then reacting the resulting polyoxypropylene glycol with ethylene oxide. The reaction is carried out in accordance with well-known procedures, see for example, U.S. Patent No. 2,674,619. For example, the polymerization of the propylene oxide is effected by condensing propylene oxide with propylene glycol or water in the presence of a basic catalyst such as sodium hydroxide, potassium hydroxide and the like. The polymerization can be carried out to any desired extent depending on the desired molecular weight of the ultimate product. The polypropylene oxide so obtained is then reacted with ethylene oxide, also in the presence of a basic catalyst if so desired.

The difunctional chain extender which is contemplated for use in the present invention has two functional groups each of which contains "active hydrogen atoms". These functional groups are in the form of hydroxyl, primary amino, secondary amino and mixtures thereof. The term "active hydrogen atoms" refers to the hydrogen which, because of their position in the molecule, display activity according to the Zerewitinoff test as described by Kohler in *J. Am. Chem. Soc.*, 49, 31-81 (1927). The difunctional chain extenders may be aliphatic, cycloaliphatic or aromatic diols, diamines or aminoalcohols. Illustrative difunctional chain extenders include ethylene glycol, propylene glycol, 1,4-butane diol, 1,3-butanediol, 1,5-pentanediol, 1,6-hexanediol, 1,10-decanediol, 1,12-dodecanediol, ethoxylated hydroquinone, 1,4-cyclohexanediol, N-methylethanolamine, N-methylisopropanolamine, 4-aminocyclohexanol, 1,2-diaminoethane, 2,4-toluenediamine and the like. In general, it is desirable to use the difunctional chain extender which has the molecular weight of 250 or less. In the practice of the present invention, aliphatic diols having molecular weight of from 50 to 250 are preferred difunctional chain extenders. Particularly preferred difunctional chain extenders are 1,4-butanediol, 1,6-hexanediol and ethoxylated hydroquinone. The difunctional extender can be a single chain extender of mixture of the above chain extenders. Where mixed chain extenders are used they can be added to the other reactants as separate components or can be preblended with either the polyester diol or polyether diol component.

In the practice of the present invention the difunctional chain extender is used in an amount of from 2 to 14, preferably from 5 to 12, most preferably from 8 to 10, moles for each mole of the mixture of the polyether diol and polyester diol.

Any of a wide variety of organic diisocyanate can be employed in the practice of the present invention, including aromatic, aliphatic and cycloaliphatic diisocyanates and mixtures thereof. Illustrative organic diisocyanates include m- and p-phenylene diisocyanates, 2,4- and 2,6-toluene diisocyanates, 4,4'-biphenylene diisocyanate, p,p'-diphenylmethane diisocyanate (MDI), 1,5-naphthalene diisocyanate, 4,4'-methylenebis(cyclohexyl isocyanate) or mixtures thereof and the like. The organic diisocyanates may contain other substituents. Aromatic diisocyanates are preferred in the practice of the present invention with p,p'-diphenylmethane diisocyanate being particularly preferred.

The amount of the organic diisocyanate employed in the practice of the present invention depends on the total amount of polyether diol, polyester diol and difunctional chain extender and should be a molar equivalent to said reactants so that there are essentially no unreacted isocyanate and hydroxyl groups remaining in the reaction product. Of course small excess of either unreacted hydroxyl or isocyanate groups may be tolerated but the properties of the reaction product may suffer somewhat. Conveniently, the mole ratio of the organic diisocyanate to the polyester diol/polyether diol/chain extender mixture is from 0.94:1 to 1.10:1, preferably 0.95:1 to 1.10:1, more preferably from 0.99:1 to 1.07:1, most preferably from 0.99:1 to 1.04:1.

The thermoplastic polyurethanes of the present invention can be prepared according to several different known methods. In the so called "one shot" method, the polyester diol, polyether diol, organic diisocyanate and difunctional chain extender and other additives, if any, are simultaneously mixed and reacted at an

elevated temperature. Another method involves the so called "prepolymer" method in which the mixture comprising the polyester diol and polyether diol is first reacted with the organic diisocyanate to form a diisocyanate-terminated prepolymer and subsequently this prepolymer is reacted with the difunctional chain extender. Yet another method that can be used involves so called "quasi-prepolymers" method. Variations  
 5 of the above methods can also be used such as first reacting the difunctional chain extender with the organic diisocyanate and then reacting the resulting products with the polyester diol and polyether diol.

Thermoplastic polyurethanes of the present invention can be prepared using the aforementioned overall ratios of the reactants over a wide temperature range, e.g., from about 20°C to about 240°C, and higher. The reaction can be conducted in bulk or in a solvent such as dimethylformamide. The reaction can be a  
 10 "one shot" or a step-wise process ("prepolymer" method) can be used. The reaction in bulk is usually conducted at a temperature of from 160°C to 240°C for a period of time ranging from several seconds to several minutes. The reaction in a solvent is conveniently at a temperature of from 40°C to 160°C for a period of time of from several minutes to several hours. The resulting partially cured polyurethane can be cooled, diced and stored and is suitable for fabricating into finished parts via techniques such as extrusion,  
 15 injection molding compression molding, and similar methods familiar to the industry.

It is often desirable, but not essential, to include a catalyst in the preparation of thermoplastic polyurethanes of the present invention. Any of the catalyst conventionally used in the art to catalyze or accelerate the reaction of an isocyanate with a reactive hydrogen-containing compound can be used for this purpose: see, e.g., Saunders et al, Polyurethanes, Chemistry and Technology, Part I, Interscience, New  
 20 York, 1963, pp. 228-232; see also Britain et al, J. Applied Polymer Science, 4, 207-211, 1960. Such catalysts include organic and inorganic acid salts of, and organometallic derivatives of, bismuth, lead, tin, iron, antimony, uranium, cadmium, cobalt, thorium, aluminum, mercury, zinc, nickel, cerium, molybdenum, vanadium, copper, manganese and zirconium, as well as phosphines and tertiary organic amines. Illustrative of such catalysts are stannous octoate, stannous oleate, dibutyltin dioctoate, dibutyltin dilaurate, cobalt  
 25 naphthanate, tetramethyltin, triethylamine, triethylenediamine, N,N,N',N'-tetramethylenediamine, N,N,N',N'-tetraethylenediamine, N-methylmorpholine, N-ethylmorpholine, N,N,N',N'-tetramethylguanidine, N,N'-diethylethanolamine and the like. The amount of the catalyst employed is that amount which will effectively catalyze the reaction of hydroxyl containing compounds with the aromatic diisocyanate. The specific amount will depend on the particular reactants and catalyst being employed. Generally, the amount of the  
 30 catalyst used is within the range of 0.0001 to 0.1 percent by weight based on the total weight of the reactants.

If desired, the thermoplastic polyurethanes of the present invention can have incorporated in them, at an appropriate stage of preparation, additives such as pigments, fillers, lubricants, stabilizers, antioxidants, fire retardants, mold release agents, synthetic rubbers and the like which are commonly used in conjunction  
 35 with polyurethanes.

The thermoplastic polyurethanes of the present invention have considerably improved abrasion resistance while retaining other desirable mechanical properties including high impact at low temperatures and good creep properties. The thermoplastic polyurethanes of the present invention are useful in the manufacture of wide variety of products requiring high abrasion resistance such as ski boots and bindings,  
 40 shoe soles, particularly sport shoe soles, various automotive uses such as in car bumpers and side panel guards, oil seals, conveyor belts and screens used by mining industry and the like.

The abrasion resistance of the thermoplastic polyurethanes of the present invention is measured in the test developed in Europe for hot stamped shoe heel pieces. This test is significantly more severe than the commonly used DIN 53516 abrasion test in that the test specimens are subjected to considerably higher  
 45 abrasion and temperature conditions. The test procedure used for measuring the abrasion properties of polyurethanes of this invention is as follows.

A test specimen (2x2 cm; weighing 2.30-2.40 g) is attached to the middle of a 50cm long abrasion contact arm. The contact arm is movably attached at one end. The specimen is then brought into contact with the abrasive contact surface of an abrasive wheel which rotates at a speed of 56 r.p.m. (rotations per  
 50 minute) for a period of time of about 30 minutes. The abrasion wheel employed is manufactured by the Rappold Schleifmittel Industrie, Vienna, Austria, firm and is 35 cm in diameter with the abrasion contact surface 6.3 cm wide. The contact of the test specimen with the abrasion contact surface of the abrasion wheel is carried out under a pressure force of 17.2 N/cm<sup>2</sup> brought by applying a weight load of 3.5 kg to the free end of the contact arm. After about 10 minutes, the contact of the test specimen with the abrasive  
 55 surface is discontinued and the test specimen is weighed. The weight loss experienced by the test specimen is indicative of the abrasion resistance property of the tested material. The lower the weight loss, the higher the abrasion resistance property of the specimen material. The test simulates much better severe abrasion conditions to which materials used for the manufacture of ski boots and sport shoe soles are

subjected to under normal use of these articles than the DIN 53516 test in that it involves both the heat buildup and severe abrasion force.

Various terms, abbreviations and designations used in the examples are explained hereinbelow.

DIOL BA-2000 stands for poly(butylene adipate) diol having the molecular weight of 2,000 sold by Poliol

5 Chimica under the trademark Bester 80.

POCD-1250 stands for poly(oxypropyl) diol having the molecular weight of 1250.

PTMEG-2000 stands for poly(tetramethylene oxide) glycol having the molecular weight of 2,000 sold by Du Pont under the trademark Theratane 2000.

PTMEG-2900 stands for poly(tetramethylene oxide) glycol having the molecular weight of 2,900.

10 BD stands for 1,4-Butanediol.

HEQ stands for ethoxylated hydroquinone.

MDI stands for p,p'-diphenylmethane diisocyanate sold by The Dow Chemical Company under the trademark ISONATE 125 M.

In the Examples, the general procedure for preparing thermoplastic polyurethanes is as follows.

15 The appropriate polyester diol, polyether diol and difunctional chain extender are dried at about 100 °C to 120 °C under about 20-30 mm Hg pressure for about 60 minutes. The dried mixture of the polyester diol and polyether diol is then fed into a twin-screw extruder feed zone along with the difunctional chain extender and melted organic diisocyanate which are fed into the zone through different conduits. At the same time catalyst is added to the feed mixture stream, if desired. The reaction is then carried on about  
20 210 °C to 240 °C for several seconds and the material extruded onto a cooled conveyor belt, and through a cold water bath before dicing. The diced pellets are dried about 2-4 hours at about 70 °C. The material is then injection molded to form test specimen measuring 2x2 cm and weighing 2.30-2.40 g.

## 25 Examples

Using the above-detailed procedure and the reactants and proportions set forth in Table I below, there were prepared thermoplastic polyurethane materials in separate experiments and various physical and mechanical properties were determined in accordance with established methods. The data are set out in  
30 Table I below

Table 1

The data in Table I clearly demonstrate surprisingly improved severe resistance properties of the thermoplastic polyurethanes of the present invention over the prior art. In addition, the other mechanical properties are about the same as those of the prior art while impact at low temperature and creep properties are considerably better.

## Claims

1. A thermoplastic polyurethane having high resistance to severe abrasion forces, said thermoplastic polyurethane comprising the reaction product of (1) a mixture of (a) 0.86 to 0.98 mole equivalent of a polyester diol having the molecular weight of from 650 to 5,000 and (b) 0.02 to 0.14 mole equivalent of a polyether diol having the molecular weight of from 2,000 to 5,000, and (2) a difunctional chain extender with (3) an organic diisocyanate.

2. The thermoplastic polyurethane of Claim 1 wherein said polyester diol has the molecular weight of from 1,000 to 3,000 and said polyether diol has the molecular weight of from 2,000 to 3,000.

3. The thermoplastic polyurethane of Claim 2 wherein said polyester diol is poly(butylene adipate) diol or poly(oxypropyl) diol and said polyether diol is poly(ethylene oxide) diol, poly(propylene oxide) diol or poly(tetramethylene oxide) diol.

4. The thermoplastic polyurethane of any one of Claims 1-3 wherein said difunctional chain extender is amine, an aliphatic diol or ethoxylated hydroquinone having the molecular weight of from 50 to 250.

5. The thermoplastic polyurethane of any one of Claims 1-4 wherein 2 to 14 moles of said difunctional chain extender is employed for each mole of the mixture of said polyester diol and said polyether diol.

6. The thermoplastic polyurethane of any one of Claims 1-5 wherein said organic diisocyanate is an aromatic diisocyanate and wherein 0.95 to 1.10 moles of said aromatic diisocyanate is employed for each mole equivalent of said polyester diol, said polyether diol and said difunctional chain extender, combined.

7. The thermoplastic polyurethane of Claim 1 comprising the reaction product of (1) a mixture of (a) 0.88 to 0.925 mole equivalent of poly(butylene adipate) diol having the molecular weight of 2,000 and (b) 0.075 to 0.12 mole equivalent of poly(tetramethylene oxide) diol having the molecular weight of 2,000 and (2) 1,4-butanediol with (3) p,p'-diphenylmethane diisocyanate.

8. The thermoplastic polyurethane of Claim 1 comprising the reaction product of (1) a mixture of (a) 0.88 to 0.925 mole equivalent of poly(butylene adipate) diol having the molecular weight of 2,000 and (b) 0.075 to 0.12 mole equivalent of poly(tetramethylene oxide) diol having the molecular weight of 2,900 and (2) 1,4-butanediol with (3) p,p'-diphenylmethane diisocyanate.

9. The thermoplastic polyurethane of Claim 7 or Claim 8 wherein 8.8 moles of 1,4-butanediol and 9.4 to 9.88 moles of p,p'-diphenylmethane diisocyanate are employed.

10. The thermoplastic polyurethane of any one of Claims 1-9, for use in the manufacture of shoe soles, ski boots and ski bindings.

(57) The present invention concerns a thermoplastic polyurethane material which is the reaction product of (1) a mixture of (a) 0.86 to 0.98 mole equivalent of a polyester diol having the molecular weight of from 650 to 5,000 and (b) 0.02 to 0.14 mole equivalent of a polyether diol having the molecular weight of from 2,000 to 5,000, and (2) a difunctional chain extender with (3) an organic diisocyanate. These polyurethane materials exhibit high resistance to severe abrasion forces while retaining desirable mechanical properties and are useful for the manufacture of shoe soles, ski boots, ski bindings, conveyor belts and screens used by mining industry and the like.
